Neutrinoless Double Beta Decay

$$(A, Z) \rightarrow (A, Z+2) + e^- + e^-$$

Candidates : ⁴⁸Ca, ⁷⁶Ge, ⁸²Se, ⁹⁶Zr, ¹⁰⁰Mo, ¹¹⁶Cd, ¹²⁸Te, ¹³⁰Te, ¹⁵⁰Nd, and ²³⁸U

The observation of neutrinoless double beta decay will confirm the Majorana nature of the neutrino and will give information on the absolute neutrino mass scale.

CaMoO₄ Crystal

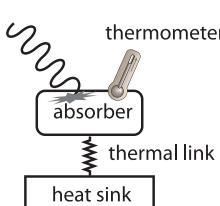

¹⁰⁰Mo (9.63% natural abundance) : one of the most promising double beta decay candidate because of its high transition energy ($Q = 3035$ keV).

CaMoO₄ (calcium molybdate) scintillators were radiopurely fabricated from single crystals by the Czochralski method.

Density (g/cm ³)	4.2-4.3
Melting point (°C)	1445-1480
Structural type	Scheelite
Wavelength of emission maximum (nm)	520

Calorimetric Detection

Energy absorption of a photon or a particle by the absorber leads to temperature increase of the system.

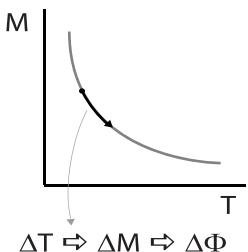

At low temperatures, the heat capacity of the detector becomes so small that even a low energy particle can sufficiently increase the

temperature of the detector. Moreover, the thermal energy fluctuation can be significantly reduced.

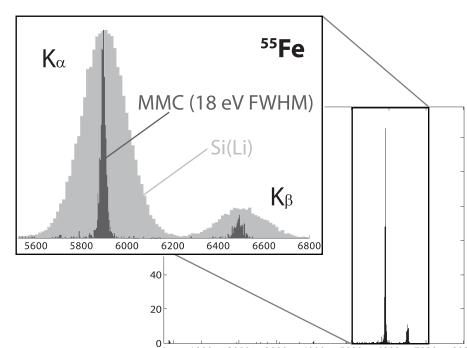

$$\Delta E = 2.35 \xi (k_B T^2 C)^{1/2}$$

Metallic Magnetic Calorimeter (MMC)

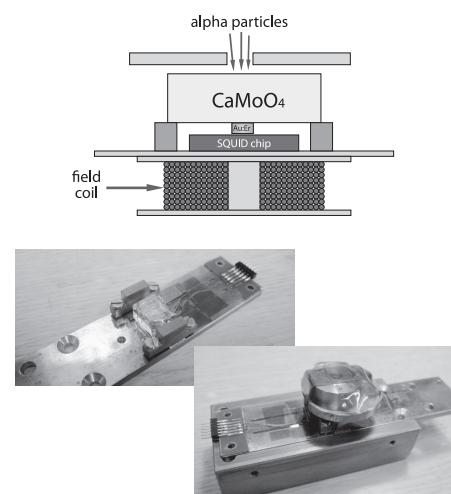

Thermometer :
Au:Er (800 ppm)
- a dilute alloy
of Er in Au
- paramagnetic
material

MMC Performance Compared with Si(Li)

Experimental Setup

Crystal size : ~ 11 mm × 8 mm × 6 mm

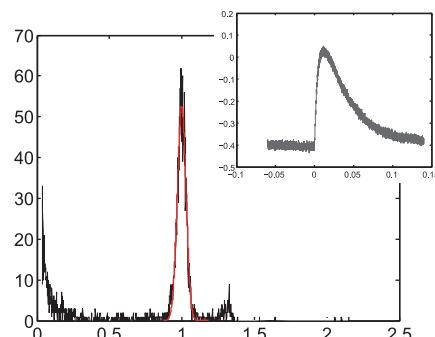

Operating condition : 11 mK, 40 G

Radioactive Source

Electro-deposited monolayer ²⁴¹Am alpha decay source from Ortec

alpha energy (kev)	5388	5443	5486
intensity (%)	1.4	12.8	85.2

Results

Trigger rate : ~ 1 Hz

Energy resolution : ~ 6.1% FWHM for the major peak

Discussion

Possible explanations for the poor energy resolution :

1) Cracks inside the crystal formed during photoresist process

↳ Adopt stressless process

2) ⁴He attached on the surface of the crystal at low temperatures

↳ Use gamma source for calibration

⌚ Future Plans :

1) Use bigger crystal

2) Measure scintillation light from the crystal at the same time using TES
